Goal and motivation

We want to be able to automatically assign tags to games, based on their description.

Solution to such problem has real-world applications, such as game grouping/filtering or finding similar games or trends analysis.

In aspect of ML project we want to make a small comparison of different models and data processing.

Your task

Goal and motivation

We want to be able to automatically assign tags to games, based on their description.

Solution to such problem has real-world applications, such as game grouping/filtering or finding similar games or trends analysis.

In aspect of ML project we want to make a small comparison of different models and data processing.

Info about the data

Steam has its own official API, from which we want to download all of the data (and since Steam is the largest library it will allow for a lot of diverse, high quality, data).

Currently there are above 100'000 games, which does create a large dataset.

Data processing

- PCA (dimension reduction)
- t-SNE (dimension reduction)
- Bag of Words - binary vector records if word appears in text (input representation)
- TF-IDF - term frequency * inverse document frequency (input representation)
- multi label binary vector (output representation)

Models

- Baseline
 - KNN
 - Logistic Regression
 - Decision Trees + Random Forest
- Advanced
 - Naive Bayes

Models

- Baseline
 - KNN
 - Logistic Regression
 - Decision Trees + Random Forest
- Advanced
 - Naive Bayes

Evaluation

- Recall $TP/(TP+FN)$ - we prefer to have more FN than to have an TP
- F1-score $(2 * precision * recall) / (precision + recall)$ - nice name, but also it combines precision with recall thus both TP and FN are equally expensive

**Me, everytime I start training
a model:**

Something funny
